INTRODUCTION

The subject matter herein contained is a descriptive review and test, taken during the winter of 1902-1903, of the central heating system of the Urbana Light, Heat and Power Company, located at Urbana, Illinois.

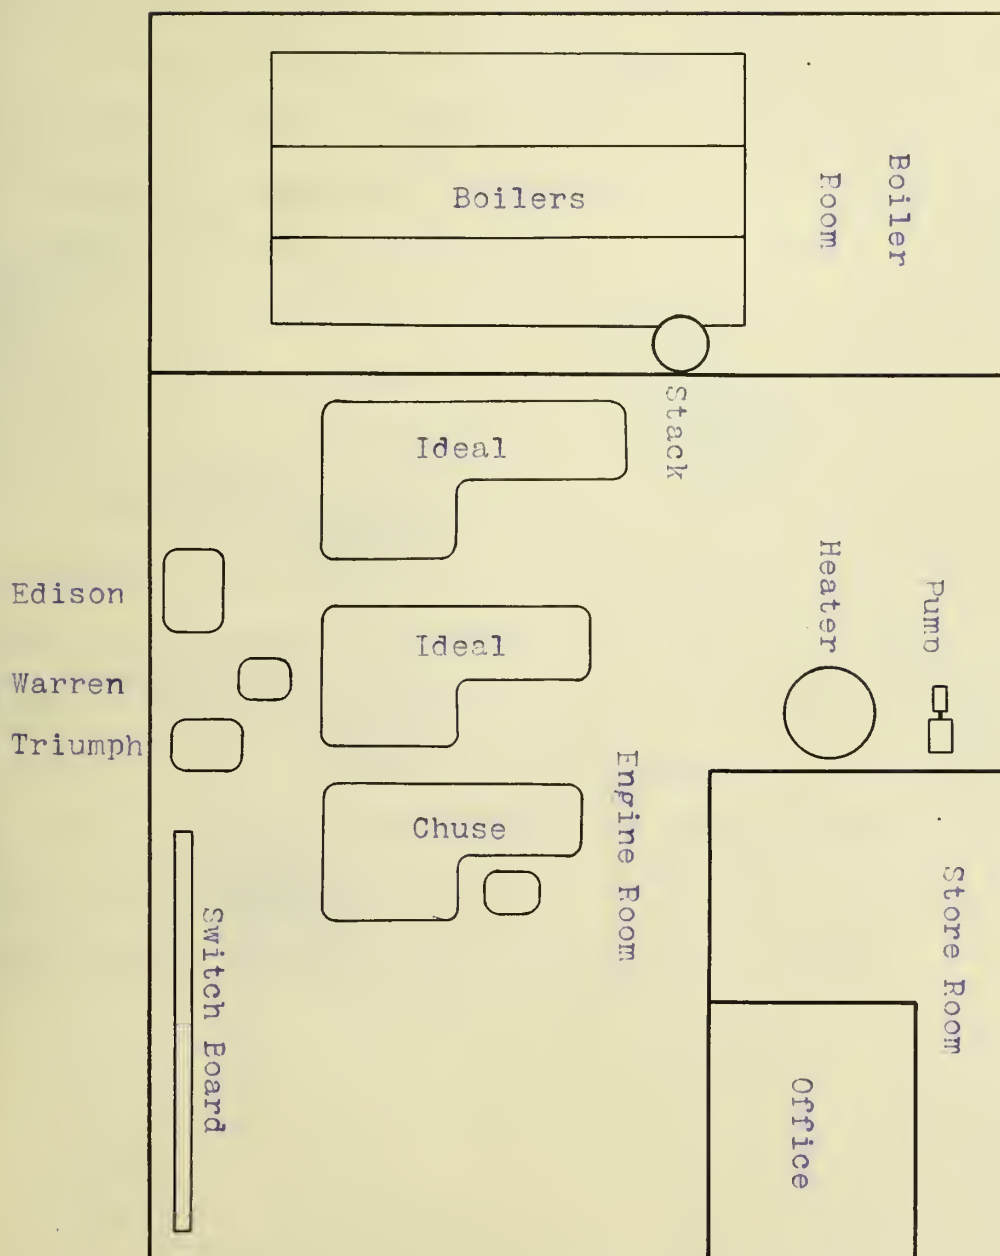

DESCRIPTION OF SYSTEM.

Located at the corner of Water and Walnut Streets, in a forty by ninety-five foot one story brick building, is contained the entire mechanical equipment of the central station which supplies light, heat and electrical power to the City of Urbana. In the rear of this building are three similar horizontal multi-tubular hand fired boilers, made by the Murray Iron Works of Burlington, Iowa. The principal features of each boiler are exhibited in the following table:-

1	Rated horse power -----	150
2	Length of boiler ----- in feet -----	18
3	Diameter of shell ----- " " -----	6
4	" " flues ----- " inches -----	4
5	Number of flues -----	72
6	Grate area ----- in square feet -----	32
7	Boiler heating surface ----- " " " -----	1587
8	Ratio of grate area to heating surface -----	1:48
9	Square feet of heating surface per rated horse power -	10.6

The draft for these boilers is furnished by a 110-foot steel stack, four feet in diameter.

Steam is conveyed from the boiler room through an eight inch main into the engine room to a steam separator, and then is distributed to the different engines. The following sketch shows the general arrangement of the plant.

The 200 H. P. 16 X 16 inch "Ideal Special" engine shown in the sketch, made by the A. E. Ide & Sons Engine Co. of Springfield, Illinois, is direct connected to a 120 K. W. 220-2200 volt alternating current generator, manufactured by the Warren Electric Manufacturing Co., of Sandusky, Ohio. This unit is rated to run at 257 revolutions per minute. A 9-1/4 K. W. Warren exciter running at 1500 revolutions per minute is belted to this engine.

South of this is another engine of the same make, with a 13 X 13 inch cylinder, running at 200 revolutions per minute, developing 100 H. P. and direct connected to a 60 K. W. 220-2200 volt alternating current Warren generator. This engine also furnishes power to a 45 K. W. 500 volt direct current Edison generator, running at 1000 revolutions per minute, as well as to a 9-1/4 K. W. Warren exciter similar to the one connected to the larger unit.

The power equipment of the plant is completed by a 90 horse power engine which has a 12 X 13 inch cylinder and runs at 257 revolutions per minute. This engine was made by the Chuse Engine Co. of Mattoon, Illinois. It is also direct connected to a 60 K. W. 220-2200 volt Warren alternating current generator and belted to a 35 K. W. 500 volt direct current generator, manufactured by the Triumph Electric Co., of Cincinnati, Ohio. An 8-1/2 K. W. 110 volt direct current Warren exciter is also run by this engine.

INTERIOR OF ENGINE ROOM LOOKING NORTH.

SWITCH BOARD LOOKING WEST.

AUXILIARY MACHINERY.

When the exhaust from the engines is only partially used or when the heating system is not in operation, it is conveyed through an eight inch pipe into a Stillwell-Bierce and Smith-Vaile Co's. feed water heater, and from here into a vertical pipe through the roof. The heater is so arranged that water may be taken either from the city main or the return main from the heating system. From here the water is fed to the boilers by a 3-2/3" X 5-1/4" X 6" Stillwell-Bierce and Smith-Vaile steam pump number 3388. The plant is also equipped for emergencies with two Pemberthy injectors; one with 1-1/4 inch and the other with 1-1/2 inch connections.

DESCRIPTION OF THE MAINS.

The main consists essentially of 427 feet of eight inch, 178 feet of seven inch, 420 feet of six inch, 350 feet of four inch and 150 feet of three inch wrought iron pipe. This is covered with asbestos and enclosed in a cylindrical tin-lined sectional wood casing tightly bound with spirally wound wire. This casing has a shell of four inches with a dead air space of one inch between the tin and asbestos. It is thoroughly covered with asphaltum, pitch and sawdust. The main was manufactured and installed by the American District Steam Co. of Lockport, New York. The accompanying figure shows the casing ready for the steam pipe.

CHAPTER II

THE first thing that struck me when I stepped out of the train

was the feeling of being in a new world. It was a feeling

activity. The streets were crowded with people, and the

air was filled with the sound of car horns and the

noise of the city. It was a feeling of being in a new

world, a world of new people and new things. I had

never before seen a city so full of life and activity.

The first thing that struck me when I stepped out of the

CHAPTER III

The first thing that struck me when I stepped out of the

train was the feeling of being in a new world. It was a

feeling of being in a new world, a world of new people

and new things. I had never before seen a city so full

of life and activity. The streets were crowded with

people, and the air was filled with the sound of car

horns and the noise of the city. It was a feeling of

being in a new world, a world of new people and new

things. I had never before seen a city so full of life

and activity. The streets were crowded with people, and

The main is buried in the earth at a depth varying from three to seven feet.

To provide for the linear expansion and contraction of the main due to the change of the temperature which it undergoes, there are placed at intervals of about one hundred feet, an automatic device called a variator. Expansion and contraction is provided for in these by copper diaphragms. The variators used are of two

DOUBLE VARIATOR

styles, the double and the single; the former being installed only in sections of the main between two fixed points one hundred feet or less apart and the latter is used where slight angles or deviations from a straight line are desired and for lengths of not over fifty feet. The accompanying cuts show the two different types.

At street corner intersections specially constructed flanged crosses are installed which have openings for continuance of the mains at right an-

gles. Cut-off valves are bolted to the crosses; the anchorage cross and its corresponding

SINGLE VARIATOR

ANCHORAGE CROSS

valve being shown in the cut at the left and

the one below. A sectional view is shown below of a portion of the main as laid in the ground with an anchorage cross with valves in position at the left, a double variator at the center and a customer's branch at the right. The amount of masonry required in the installation of such a main is clearly shown in the view. Service mains taken from the top of the street mains are carefully graded upward from the connection to the building to be heated.

Valve Under drainage for the line is provided by means of a drain tile, so that the casing will not at times be surrounded by water from springs, leaky water or sewer pipes. A four inch cast iron pipe which returns the water of condensation from a part of the system is laid under the street main itself.

Sectional view of the main.

BUILDINGS HEATED.

The types of buildings that are furnished with heat from the plant may be classified as public buildings, stores and offices. All of these are built of either brick or stone.

The principal features of the buildings as regards cubical contents, external wall surface, glass area and radiation installed, is exhibited in the following table, columns one to six inclusive. Columns seven to ten inclusive are added for the purpose of showing the relation of the actual radiation surface to that which would be required if calculated by Mill's rule. A fuller explanation and the uses of this rule may be found in Mill's "Warming and Ventilation of Buildings", volume II page 478. Column eleven was calculated by dividing column one by column six, and it shows the number of cubic feet of space heated by one square foot of actual radiation surface in the different buildings.

JOHNSON REGULATING SYSTEM.

The Johnson system of temperature regulation is installed in the Champaign County Court House which is one of the buildings on the return system. Its operation is very simple and will be described briefly in the following lines.

Compressed air is the motive power which operates the valves or dampers used for this temperature regulation, since it is the most useful of power mediums for the circumstances under which the system must work. The air pressure is obtained by means of utilizing the water pressure in the building as power for the compressor, which is shown by the accompanying figure. Suffice it to say that one of the pipes at the bottom of figure 1 is connected to the water supply of the building and the other pipe to the waste; the pipe shown at the top being connected to the air pipes of the building. The compressor automatically compresses the air to about ten pounds per square inch and then moves only as the air is used, the amount of water consumed being extremely small.

The temperature regulation is affected by means of a thermostat, placed on the wall of the room heated, which controls the source of heat. This thermostat, shown in a side view in figure 2, is connected to the compressor; before mentioned, and to a diaphragm valve, figure 3, which in turn is connected to the radiator at the entrance of the steam pipe by small air pipes in the wall of the building.

Figure 1

Figure 2

The metallic strip O shown in figure 2 is made up of two pieces of very thin strips of steel and brass, and since brass expands and contracts more readily than steel from the heat and cold, the strip O will be varied to the right or left when the temperature rises or falls. By this variation the different levers either open or close the valve N, which in turn increases or decreases the air pressure, and thus actuates the diaphragm F shown in figure 3. Taking the case of the temperature rising, i.e. of O figure 2 moving to the left, the air pressure on the diaphragm F will increase and the valve B figure 3 will be lowered; thus shutting off the steam

supply and allowing the room temperature to fall. Then when the temperature falls the opposite action takes place in the thermostat; thereby keeping a nearly constant room temperature by this continuous operation. The thermostat is generally set to operate at 70 degrees Fahrenheit.

COOLING OR ECONOMIZING COILS.

The heat from the water of condensation is utilized from the greater part of the system by returning it to the plant through cast iron mains to be used as feed water for the boilers. In the places where this method is not employed, economizing coils are used. Cast iron not being affected by the chemical properties of hot water, a continuous circulating economizing or cooling coil is placed in each building heated, and all water of condensation is discharged into it from the steam trap. The coil is generally placed in a tin-lined box having an inlet for fresh air and an outlet for hot air leading to a register placed in the floor above. The water leaves the coil a few degrees warmer than the temperature of the surrounding air and is then thrown into the sewer. The cut shown below is a semi-sectional view of the coil.

ECONOMIZING
COIL

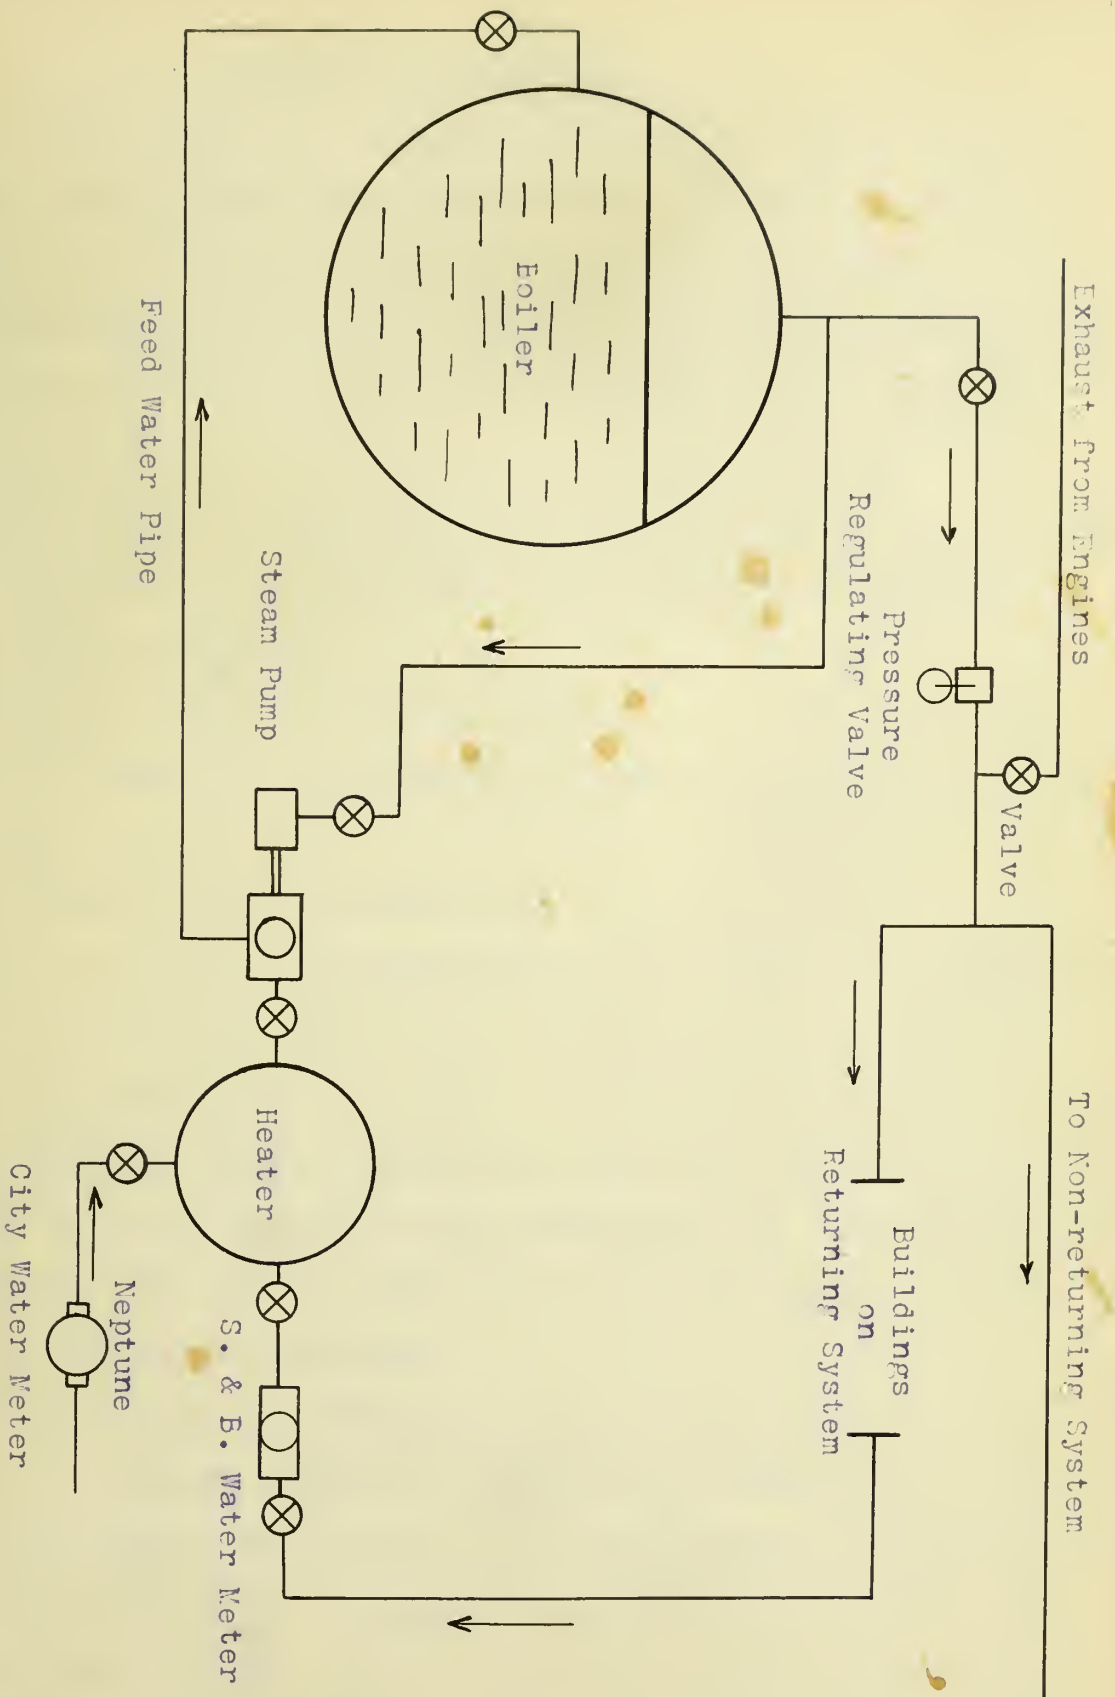

Tests on the whole system.

OBJECT

The tests on the whole system were taken to determine the amount of water condensed per square foot of radiation under various temperature conditions and to find the boiler horse power required for the system under these conditions.

DESCRIPTION OF APPARATUS

The diagram on the following page shows the water circuit of the heating system. Both the city water and the return water of condensation were used in feeding the boilers. The Schaeffer and Budenburg meter registered the amount of water condensed in the returning system. Since the returned water was insufficient to keep the water-level in the boiler constant, it was necessary to pump more water from the city main. Hence the Neptune meter registered the amount of water condensed and thrown away in the non-returning system. Thermometers were used in determining the temperature of the water of condensation, of external air, and internal temperature of the buildings on the system. The pressure in the main was determined by means of a steam gauge.

DIAGRAMATIC SKETCH OF APPARATUS.

METHODS OF PROCEDURE.

Before starting a test, we saw that the water in the two boilers was at the same height under normal conditions. Then this water level was marked by a string around the water glass. With these preliminaries, the test was begun; simultaneous readings being taken of the following gauges and instruments at given intervals:-

Time.

Schaeffer & Budenburg water meter #533 on the return main.

Neptune water meter #68374 on city water connection.

Boiler pressure.

Heating main pressure at plant.

Temperature of condensation water in return mains before entering meter.

Temperature of external air.

In addition to these, the temperatures of the rooms of the different buildings were observed at various intervals during the day; a mean of which is recorded in the results. The readings at the start and finish are the only ones of practical value; the intermediate ones being taken so as to make sure that everything was in working order throughout the test and to enable us to stop the test at any time in case of an accident or breakdown.

The amount of radiating surface in use during the test was determined by frequent visits to the buildings heated by the plant. The following sample sheet shows the method employed in the determination of the square feet of radiation in use in each room. That is, we observed what radiators were in use and compared with the data on this sheet.

TABLE OF CUBICAL CONTENTS, EXTERNAL WALL SURFACE, GLASS

AREA AND RADIATING SURFACE.

Place Herald Office Measured by Rutt & Drury Date Feb. 6, 1903.

<u>CUBICAL CONTENTS OF ROOM</u>					<u>EXTERNAL SURFACE</u>

:	:	:	:	:	:	:	414 :

For example, say radiators A and B were turned on, then referring to the sheet, the sum of the square feet of surface in A and B is the radiation in use in this particular room.

Before taking any tests, the buildings on the system were measured in order to determine the cubical contents, external wall surface, glass area, and radiating surface as the data on the preceding sheet indicates.

HERALD OFFICE PLAN.

Showing the location of radiators for reference in the table.

Item (4) = (2) divided by (1).

" (5) = (3) " " (1).

" (8) = (4) " " (6).

" (9) = (5) " " (7).

" (10) = ((4) plus (5)) divided by 1275452.

" (15) = " " " " " 30.

Tests on the mains.

OBJECT

The object of the tests made on the mains was to find the rate of condensation in pounds of water per square foot of main area per hour.

METHODS OF PROCEDURE

The tests were made in the following manner. The customers were all shut off from the main and then the steam was turned on at about the same pressure as was normally used in the tests on the whole system. When the mains had become well heated and the condensation seemed nearly uniform, the tests were begun. The time of starting being noted, the steam pressure, the temperature and weight of condensation water were observed. The condensation was measured at the plant and also at Clark's Marble Works; that from the returning system at the former and that from the non-returning at the latter. The tests were stopped in a manner similar to that above described for starting. Steam was allowed to circulate through the mains about twenty hours before the tests were made.

TEST NO. 1.

" (8) = (4) " " (6).

" (9) = (5) " " (7).

" (14) = ((4) plus (5)) divided by 30.

Auxiliary Tests on Water Rate of Installation at Columbian Hotel.

DESCRIPTION OF APPARATUS.

The apparatus used in connection with these tests consists of an American District Steam Co's. water meter #555 connected to the discharge pipe from the cooling coil to measure the water of condensation from the building. A steam gauge was attached to the steam trap to ascertain the pressure in the main. Thermometers were used to determine the temperature of condensation water, external air, and air in the building.

Photograph of meter, steam trap, and cooling coil in basement.

METHODS OF PROCEDURE.

The tests on the hotel were conducted as follows:-

The meter was read, the time noted, the steam pressure taken and the temperature of the water of condensation, external air and internal air observed. Then all the radiators were visited and the ones that were in operation noted in order that the square feet of radiation heating the building at that time could be calculated. All the readings were repeated several times during the day and each test was stopped by taking readings similar to those in starting.

CALIBRATION OF METER.

Meter #555, manufactured by the American District Steam Co. of Lockport, New York, was calibrated as follows:-

The water of condensation after passing through the meter was conveyed through a pipe to a tank balanced on a pair of scales. The rate of flow was regulated by opening or closing the radiator valves in various parts of the building. In starting a calibration test, the scales were balanced while the water was running through the valve in the bottom of the tank, and at a given signal the meter was read, the tank valve closed, and the time noted. The temperature of the water of condensation was observed frequently. To stop the test simultaneous readings were taken of the meter, time, and the weight on the scales; the latter being continually balanced throughout the test.

THE END

THE END OF THE WORLD

1. The first of the world's great religions, the Jewish religion, was founded by a man who lived in the land of Israel, and who was called Moses. He was a great prophet, and he was the first to bring the word of God to the people of Israel. He was the first to bring the word of God to the people of Israel.
2. The second of the world's great religions, the Christian religion, was founded by a man who lived in the land of Israel, and who was called Jesus. He was a great prophet, and he was the first to bring the word of God to the people of Israel.
3. The third of the world's great religions, the Muslim religion, was founded by a man who lived in the land of Arabia, and who was called Muhammad. He was a great prophet, and he was the first to bring the word of God to the people of Arabia.
4. The fourth of the world's great religions, the Buddhist religion, was founded by a man who lived in the land of India, and who was called Buddha. He was a great prophet, and he was the first to bring the word of God to the people of India.
5. The fifth of the world's great religions, the Hindu religion, was founded by a man who lived in the land of India, and who was called Krishna. He was a great prophet, and he was the first to bring the word of God to the people of India.
6. The sixth of the world's great religions, the Jain religion, was founded by a man who lived in the land of India, and who was called Mahavira. He was a great prophet, and he was the first to bring the word of God to the people of India.
7. The seventh of the world's great religions, the Sikh religion, was founded by a man who lived in the land of India, and who was called Nanak. He was a great prophet, and he was the first to bring the word of God to the people of India.
8. The eighth of the world's great religions, the Zoroastrian religion, was founded by a man who lived in the land of Persia, and who was called Zoroaster. He was a great prophet, and he was the first to bring the word of God to the people of Persia.
9. The ninth of the world's great religions, the Baha'i religion, was founded by a man who lived in the land of Persia, and who was called Baha'u'llah. He was a great prophet, and he was the first to bring the word of God to the people of Persia.
10. The tenth of the world's great religions, the Bahai religion, was founded by a man who lived in the land of Persia, and who was called Baha'u'llah. He was a great prophet, and he was the first to bring the word of God to the people of Persia.

THE END

TEST NO. 5.

COLUMBIAN HOTEL ----- APRIL 3, 1903.

1	Duration of test -----	1hr. 37min.
2	Meter reading 10:12 A. M. -----	360370 lb.
3	" " 11:49 " " -----	360860 "
4	Total water condensed (corrected) -----	482 "
5	Average " " hourly -----	298 "
6	Amount of radiation in use -----	971 sq.ft.
7	Water condensed per sq.ft. of radiation per hour	.306 lb.
8	" " " gross cu.ft. of space " " -----	.00176 "
9	Temperature of condensed water -----	123°F.
10	Average external temperature -----	29 "
11	" temperature in building -----	69 "
12	" steam pressure in main -----	2-1/2 #
13	H.P. required per hour -----	9.93

Rainy weather.

TEST NO. 6.

COLUMBIAN HOTEL ----- APRIL 22, 1903.

1	Duration of test -----	5hrs. 43min.
2	Meter reading 9:26 A. M. -----	450524 lb.
3	" " 3:09 P. M. -----	452050 "
4	Total water condensed (corrected) -----	1498 "
5	Average " " hourly -----	262 "
6	Amount of radiation in use -----	908 sq.ft.
7	Water condensed per sq.ft. of radiation per hour	.289 lb.
8	" " " gross cu.ft. of space " "	.00152 "
9	Temperature of condensed water -----	121°F.
10	Average external temperature -----	43 "
11	" temperature in building -----	69 "
12	" steam pressure in main -----	1 #
13	H. P. required per hour -----	8.75

METHODS OF CALCULATION.

Items (1), (2), (3), (6), (9), (10), (11) and (12)
are observed data.

Item (4) = (3)minus(2)multiplied by 98.2 %.

" (5) = (4)divided by(1).

" (7) = (5) " " (6).

" (8) = (5) " " 169076.

" (13) = (5) " " 30.

GENERAL RESULTS FROM ALL TESTS.

The tests on the Columbian Hotel were made mainly to determine the water-rate of the building per square foot of radiation. By so doing it was possible to check the results of the water-rate of the whole system, since this building represented the average conditions of the system. The water-rate of the returning system compared very closely with that at the hotel; but owing to the leaks in the system, to the impossibility of measuring the condensation from the engines and pump, or to the inaccuracy of observations, the non-returning system gave results somewhat high. The test on the main, although made in warm weather, indicates that a very small per cent of the heat is dissipated in the main itself.

In moderately cold weather when considering the whole system it was found that approximately one-third of a pound of water is condensed from one square foot of radiation in one hour.

CONCLUSION.

After reviewing this central heating system and making the few foregoing tests, the authors have arrived at the following conclusions.

Generally speaking, the installation is of the modern type. Situated as it is in the business center of the City of Urbana, and since the exhaust steam which is a by-product of the electric lighting and power plant is used for heating during the greater part of the year, it seems to be a good business proposition. From the fact that no complaints were heard from the consumers, the plant seems to be on the whole satisfactory and useful to the community.
